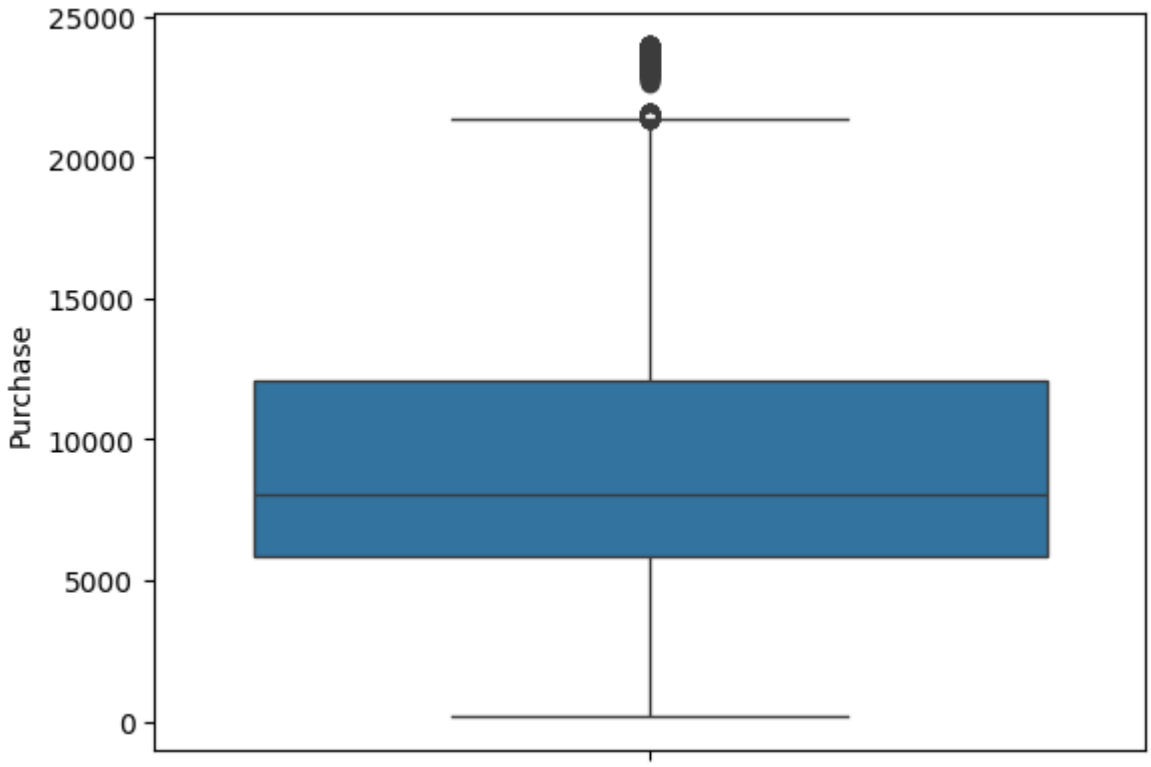
Detecting Outliers

In [16]:
```
sns.boxplot(y='Purchase',data=df)
```

Out[16]:
```
<Axes: ylabel='Purchase'>
```



Median (Q2):

The thick line inside the box is around ₹8,000. This is the median purchase amount.

Interquartile Range (IQR):

The box spans roughly from ₹5,800 (Q1) to ₹12,000 (Q3).

This tells us that the middle 50% of purchases lie in this range.

Whiskers (range of non-outlier data):

Lower whisker is around ₹200, upper whisker is around ₹21,000.

Most purchase values lie within this range.

Outliers:

The dots above the upper whisker (~₹22,000–₹24,000) are outliers.

These represent unusually high purchases compared to the majority of customers.

Skewness:

The upper whisker is longer and there are several high-value outliers → right-skewed distribution.

This means most purchases are on the lower side, with a few customers spending much more.

Spread of data:

Large IQR and extreme outliers indicate high variability in purchase amounts.

In [17]:
```
df1=df.copy()

lower = df1['Purchase'].quantile(0.05)
upper = df1['Purchase'].quantile(0.95)
df1['Purchase'] = df1['Purchase'].clip(lower, upper)
```

In [18]:
```

In [20]:

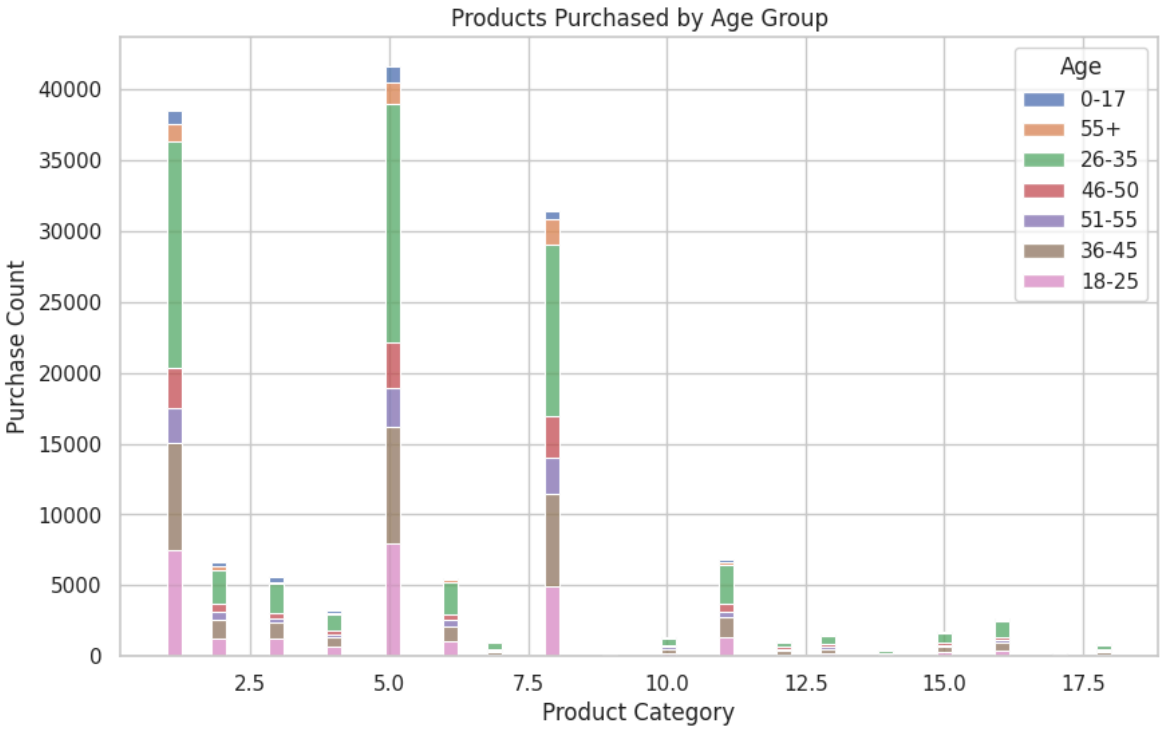
Products vs Age Groups The relationship between product categories and age groups can be visualized with a histogram of Product_Category against Age:

In [21]:
```
plt.figure(figsize=(10, 6))
sns.histplot(data=df, x='Product_Category', hue='Age', multiple='stack')
plt.title('Products Purchased by Age Group')
plt.xlabel('Product Category')
plt.ylabel('Purchase Count')
plt.show()
```



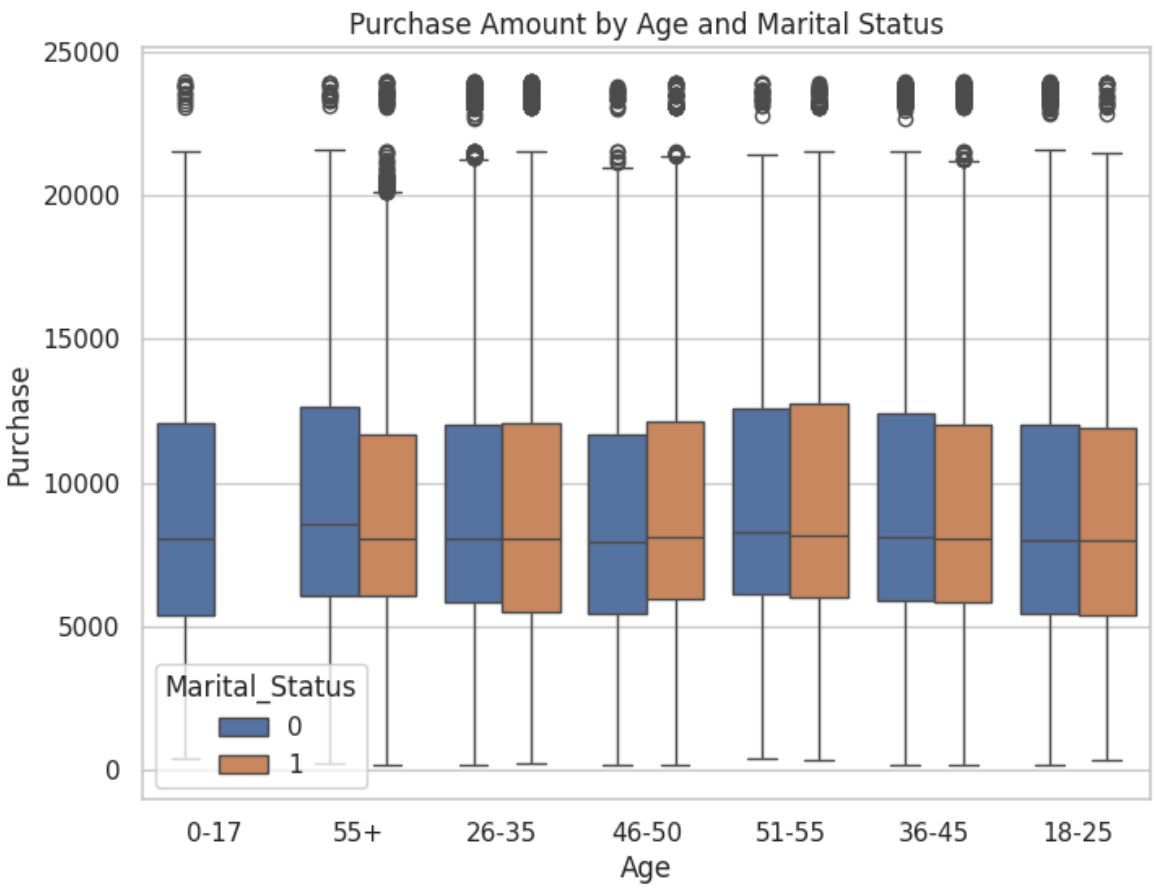
The 26–35 age group dominates purchases across almost all product categories.

18–25 and 36–45 age groups also buy actively, particularly in categories like 1, 5, and 8.

Very few purchases come from 0–17 or 55+ groups, indicating limited spending power or participation.

Relationship Between Age, Marital Status, and Amount Spent

In [22]:
```
plt.figure(figsize=(8,6))
sns.boxplot(data=df, x='Age', y='Purchase', hue='Marital_Status')
plt.title('Purchase Amount by Age and Marital Status')
plt.show()
```



Insights

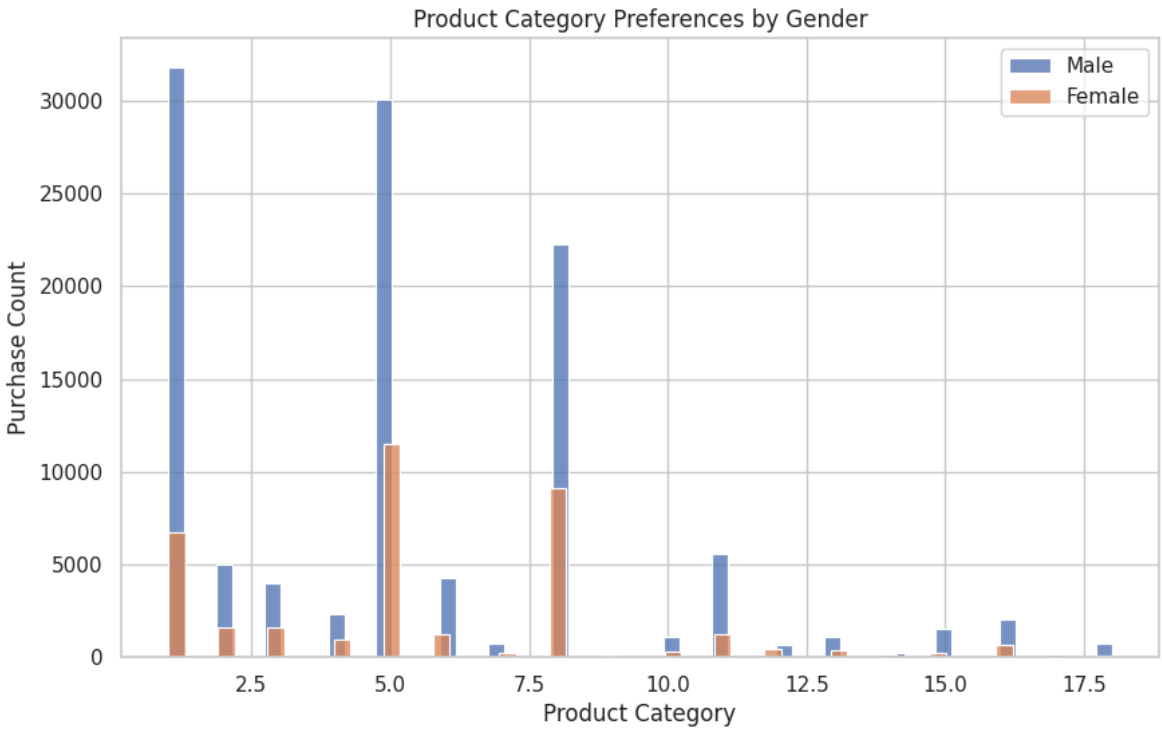
Married customers (Marital_Status = 1) tend to spend slightly more than unmarried individuals in most age brackets.

Middle-aged groups (26–45) show the highest median purchase amounts, possibly reflecting stable income levels and family needs.

Teenagers (0–17) and seniors (55+) consistently spend less overall.

Preferred Product Categories by Gender

In [23]:
```
plt.figure(figsize=(10,6))
sns.histplot(data=df[df['Gender']=='M'], x='Product_Category', label='Mal
sns.histplot(data=df[df['Gender']=='F'], x='Product_Category', label='Fem
plt.legend()
plt.title('Product Category Preferences by Gender')
plt.xlabel('Product Category')
plt.ylabel('Purchase Count')
plt.show()
```



Insights

Males dominate in total purchase volume, especially in categories 1, 5, 8, and 11.

Females show higher participation in categories 2, 3, and 4, suggesting interest in lifestyle and home goods.

Both genders overlap heavily in categories 1 and 5, indicating these are popular across all demographics.

Inferences For Gender vs amount spent

Males spend more on average (9458) than females (8725).

i)

Male CI (Full dataset width): 9508.77 – 9407.55 ≈ 101.22

Female CI (Full dataset width): 8808.46 – 8642.49 ≈ 165.97

The CI is wider for females in the full dataset.

Reason:

CI width depends on standard deviation and sample size:

Females in this dataset have a higher variance in purchase amounts (or fewer observations than males), making their CI wider.

(ii) width of the confidence interval affected by the sample size

Smaller samples (n=300) → much wider CIs (e.g., male: 1135.89 wide; female: 113.71)

Medium samples (n=3000) → narrower

Large samples (n=30000) → very close to full dataset CI

Observation:

CI width decreases as sample size increases

(iii) CIs for different sample sizes overlap

For males:

n=300 CI (8489–9625) overlaps with n=3000 CI (9307–9675) and full CI (9407–9508)

For females:

n=300 CI (9372–9486) does not overlap with full dataset CI (8642–8808)

This happens because small samples may be unrepresentative, especially for skewed distributions.

(iv) sample size affecting the shape of the distribution of means

Small sample sizes (n=300) → mean estimates are more variable → wider CIs → more "spread out" sampling distribution.

Medium to large samples (n=3000, 30000) → distribution of sample means is narrower and more symmetric → CIs shrink → approaches a Normal shape as predicted by CLT.

Observation: Increasing sample size reduces variability and makes the mean more precise.

Male vs Female: Full dataset CIs show females wider due to higher variance or smaller n.

Sample size effect: Larger n → narrower CI, more precise estimate.

Small samples can be unrepresentative, especially for females (overlapping issues).

CLT confirmed: Larger samples → sampling distribution of the mean → nearly Normal.

```

the confidence interval computed using the entire dataset wider for one of the statuses

Marital_Status Full dataset CLT 95% CI CI Width 0 (Unmarried) (9212.37, 9325.52) 113.15 1 (Married) (9492.78, 9610.35) 117.57

Observation: The CI is slightly wider for Married customers.

Reason:

CI width depends on standard deviation and sample size:

Married customers either have slightly higher variance in purchase amounts or smaller sample size than unmarried, which increases the CI width.

ii. the width of the confidence interval affected by the sample size smaller sample CIs:

Unmarried (0):

n=300 → CI width ≈ 1093

n=3000 → CI width ≈ 352

n=30000 → CI width ≈ 112

Married (1):

n=300 → CI width ≈ 1080

n=3000 → CI width ≈ 380

n=30000 → CI width ≈ 118

Observation: CI width decreases as sample size increases, consistent with the Central Limit Theorem ⟹larger n⇒smaller CI

iii. confidence intervals for different sample sizes overlap/not

Small sample sizes (n=300) have wider CIs, which may overlap or extend beyond the full dataset CI.

Medium and large samples (n=3000, 30000) mostly overlap with the full dataset CI, indicating that larger samples give more stable estimates.

Conclusion: Overlap improves with larger samples; small samples are more variable.

iv. How does the sample size affect the shape of the distributions of the means?

Small n (e.g., 300): Distribution of the mean is wide and can be skewed due to random sampling variation.

Medium n (3000): Distribution becomes narrower and more symmetric.

Large n (30000 or full dataset): Distribution is approximately Normal, narrow, and CI converges to the true population mean.

CLT Insight: Larger sample sizes stabilize the sampling distribution and reduce variability in the estimate of the mean.

Married customers spend more on average than unmarried customers.

CI width decreases with sample size, consistent with CLT.

Larger samples produce more Normal, stable distributions of the mean.

i. Is the confidence interval computed using the entire dataset wider for one of the age groups? Why?

Look at the full dataset CI widths:

Age Group CLT 95% CI Width 0-17 532.92 18-25 198.80 26-35 138.27 36-45 194.79 46-50 298.09 51-55 334.86 55+ 431.95

Observation: The CI is widest for 0-17 and narrowest for 26-35.

Reason:

CI width depends on standard deviation and sample size:

Younger age group (0-17) likely has smaller sample size or higher variance in purchase amounts, leading to a wider CI.

Age 26-35 probably has more data points and lower variance, producing a narrower CI.

ii. the width of the confidence interval affected by the sample size?

From the sample-based CIs:

Small sample (n=300) → very wide CIs

Medium sample (n=3000) → moderately narrower CIs

Large sample (n=30000) → narrow, close to full dataset CI

Conclusion:

Larger sample sizes reduce the width of the confidence interval.

iii. confidence intervals for different sample sizes overlap/not

For small samples (n=300), CIs are very wide and can extend beyond the full dataset CI.

For medium (n=3000) and large (n=30000) samples, CIs mostly overlap with the full dataset CI.

CLT Insight:

Increasing sample size stabilizes the mean estimate, reduces variability, and produces a distribution closer to Normal.

Summary Table (Age Groups) Age Group Full CI Width Observations 0-17 532.92 Smallest n or high variance → widest CI 18-25 198.80 Moderate CI width 26-35 138.27 Narrowest CI, likely largest n / low variance 36-45 194.79 Moderate CI width 46-50 298.09 Slightly wider CI 51-55 334.86 Wide CI, small sample? 55+ 431.95 Wide CI, possibly high variance

Interpretation:

Age affects spending: Average purchase amount differs by age.

Younger (0-17) and older (55+) have more uncertain mean estimates → wider CIs.

Middle ages (26-35) have more stable mean estimates → narrow CI.

Larger sample sizes consistently reduce CI width and make the mean estimate more reliable.

Walmart Customer Spending Analysis Report

Gender-based Spending

CLT 95% Confidence Intervals (Full Dataset)

Gender CI (Lower, Upper) Male (9407.55, 9508.77) Female (8642.49, 8808.46)

Overlap Analysis:

Male CI: 9407 - 9508

Female CI: 8642 - 8808

There is no overlap between male and female confidence intervals.

Interpretation & Actionable Insights:

Males spend more on average than females in the dataset.

Walmart can leverage this insight by:

Designing targeted promotions for female customers to increase engagement and average order value.

Offering gender-specific product recommendations.

Optimizing marketing budgets towards groups with lower spending to boost revenue.

Marital_Status-based Spending

CLT 95% Confidence Intervals (Full Dataset)

Marital Status CI (Lower, Upper) Unmarried (0) (9212.37, 9325.52) Married (1) (9492.78, 9610.35)

Overlap Analysis:

Unmarried CI: 9212 – 9325

Married CI: 9492 – 9610

There is no overlap between unmarried and married confidence intervals.

Interpretation & Actionable Insights:

Married customers spend more on average than unmarried customers.

Walmart can leverage this insight by:

Offering family-oriented or bulk promotions for married customers.

Targeting special occasions or household products for married groups.

Running personalized discounts for unmarried customers to increase their average spending.

Age-based Spending

Most age groups overlap partially except for 51-55, which has the highest spending CI (9525–9859).

0-17 and 51-55 groups show the largest difference in average spending, with little overlap between the extremes.

Interpretation & Actionable Insights:

Age affects spending, and middle-aged and older adults tend to spend more.

Walmart can leverage this insight by:

Running age-targeted campaigns (e.g., 51-55 for premium products, 0-17 for kids' products).

Offering personalized discounts or loyalty programs for age groups with lower average spending.

Using age segmentation for inventory planning, product launches, and marketing.

Summary Factor Overlap? Key Insight Walmart Actionable Steps Gender No Males spend more than females Targeted promotions, gender-specific marketing Marital Status No Married customers spend more Family-oriented offers, personalized campaigns Age Group Partial Middle-aged/older adults spend more Age-targeted marketing, personalized discounts

Conclusion: Walmart can use these insights for targeted marketing, personalized offers, and inventory planning to optimize revenue and customer satisfaction.

Insights

Males spend more per transaction than females (non-overlapping CIs).

Married customers spend more than unmarried.

Older age groups (51-55, 55+) have higher average spend.

As sample size increases, CI width decreases → more reliable estimates.

Purchase distribution is right-skewed; few large transactions drive up mean.

Recommendations

Introduce targeted promotions for female customers to raise AOV.

Launch premium bundles or loyalty perks for married customers.

Focus marketing on older, higher-spending age segments.

Use age & gender-based personalization in ads and offers.
